GUAM
EROSION & SEDIMENT CONTROL
FIELD GUIDE

Version 2.0 for
Contractors and
Site Inspectors
2017
Purpose
This field guide was designed specifically for contractors in Guam involved in clearing, grading, stockpiling, and other earth-moving activities at all construction sites. Its requirements will be administered and enforced pursuant to the Guam’s National Pollution Discharge Elimination System (NPDES) permit requirements; Water Quality Standards; and Soil Erosion and Sediment Control Regulations (22GAR-2 Chapter 10). To help contractors implement erosion and sediment control standards of the 2006 CNMI/Guam Stormwater Management Manual, this field guide:

▪ Explains why ESC is an important part of the construction process
▪ Summarizes ESC practice design, installation, and maintenance tips
▪ Outlines inspection and project closeout considerations
▪ Serves as a reference for use in the field
▪ Relies primarily on graphical illustrations for multi-lingual users
▪ Is not a substitute for more detailed practice design or technical specifications

Prepared for:
Version 2.0 prepared for the Guam Contractors Association Trades Academy by the Horsley Witten Group under contract with the NOAA Coral Reef Conservation Program. September 2017

Version 1.0 was originally prepared in 2012 for the Guam Coastal Management Program and Guam Environmental Protection Agency by the Horsley Witten Group under contract with the Center for Watershed Protection. Funding was provided by the National Oceanic and Atmospheric Administration, US Department of Interior, and US Environmental Protection Agency.

To protect the environment and fulfill your responsibilities, it is important to understand why ESC is a critical part of the construction process.
Impacts of Construction

There is a direct link between land alteration and the health of streams, wetlands, coastal waters, and aquifers. The conversion of vegetated areas to buildings, roads, and parking lots changes surface and groundwater drainage processes, which can have a negative impact on our local environment and economy. These impacts begin during construction and are influenced by rainfall, site conditions, and our ability to apply proper erosion and sediment control (ESC) practices.
Before clearing and grading, native vegetation absorbs rainfall, slows runoff velocities, protects soil from erosion, and allows for infiltration into the ground.

Land cleared for new development involves removal of vegetation, exposure of valuable soil, and compaction by heavy equipment. These factors result in more surface runoff and less recharge to important aquifers.

Sediment buildup can clog drainage systems and lead to flooding of roadways and properties.

Sediment-laden runoff ultimately discharges into streams, wetlands, and marine waters. Sediment particles carry toxic pollutants and nutrients that can reduce water quality.
When it rains on construction sites, unprotected slopes and **exposed soils can erode.** If ESC practices are not properly installed or maintained on site, sediment runoff can wash into roads, adjacent properties, and waterways.

Runoff from steep or highly **erodible roads** can add to the sediment load from construction sites during typical storm events.

Sediment deposition can damage nearshore ecosystems by filling shallow wetlands and smothering benthic habitats such as **coral reefs.**

Turbidity **reduces oxygen** and light necessary for marine life.
Site Factors Contributing to Erosion

Several factors contribute to increased erosion at construction sites (Figure 1.1). Erosion and sediment loss is more likely to occur when:

▪ Native vegetation is removed, and soils are exposed to erosive rainfall and surface runoff.

▪ Erodible soils are present. Most soils in Southern Guam are classified as volcanic rock that have a higher erosion potential and are less permeable than the limestone in Northern Guam.

▪ Steep slopes exist on site. Unlike flat terrain, water concentrates and travels faster down steep slopes. Sediment on cut and fill slopes is particularly vulnerable to erosion.

▪ ESC practices are not properly installed or maintained. This field manual describes appropriate techniques to prevent erosion and reduce sedimentation.

▪ Heavy rainfall occurs, especially during the rainy season (July through October). Average annual rainfall on Guam ranges from ~85-115 inches (Figure 1.2).

Figure 1.1. Factors contributing to construction site erosion (Adapted from: Tetra Tech).
Figure 1.2. Annual Rainfall in inches per year for Guam (Adapted from Gingerich's 2003 USGS Report WRIR 03-4126, Hydrologic Resources of Guam).
ESC Regulations

Stormwater runoff from construction sites is primarily regulated by the Guam EPA, Guam Department of Public Works, and the US EPA. GAR Title 22 Chapter 10 - Guam Soil Erosion and Sediment Control Regulations and Chapter 45 - Soil Erosion and Sedimentation Control) can be downloaded at www.epa.guam.gov. Most land disturbing activities on Guam require one or more of the following:

1. **Clearing, Grubbing, Grading and Stockpiling Permits.** DPW (with Guam EPA review) issues permits for any alteration to Guam’s environment including clearing an area, grading or stockpiling debris. Permit applications can be found at the DPW One Stop Center in Upper Tumon. Federal projects must apply for this clearance directly at Guam EPA.

   If the proposed project is ≥ 1 acre, the applicant must apply for coverage under the Construction General Permit (CGP) through US EPA.

2. **Environmental Protection Plans (EPP)** are required by Guam EPA for most clearing, grading and marine related construction work. EPPs describe the proposed methods of manual and mechanical work, potential environmental impacts, and methods of minimizing those impacts such as an erosion control plan. The EPP should be developed by a professional engineer.

3. **Erosion Control Permits** are reviewed by Guam EPA as part of the Clearing and Grading permit process. These plans, which are aimed at protecting the water quality of the closest body of water.
4. **401 Water Quality Certification (WQC).** Guam EPA reviews and certifies federal permits for compliance with all local regulations and policies and in accordance with the Guam Water Quality Standards.

5. **Federal NPDES Regulations.** On Guam, the USEPA administers the National Pollutant Discharge Elimination System (NPDES), which was established under the federal Clean Water Act to protect our nation’s waters from various types of pollution, including temporary discharges from construction activities. In January 2017, the updated Construction General Permit (CGP) was issued (www.epa.gov/npdes/stormwater-discharges-construction-activities). To gain coverage, the following conditions must be met:

- All construction project sites disturbing ≥ 1 acre must submit a Notice of Intent (NOI) to the USEPA using the online NPDES eReporting Tool for the CGP and furnish a copy to Guam EPA.
- All projects disturbing ≥ 1 acre must prepare and implement a Stormwater Pollution Prevention Plan (SWPPP) in accordance with the NPDES Stormwater Program.
- Permit applies to stormwater discharges from construction support activities, as well as earth disturbing activities associated with staging areas and access roads.
- Technology-based effluent standards now apply. Additional requirements if you drain to an area of known water quality impairments or endangered species.

The US Department of Defense may have additional requirements for military projects.

The Guam Coastal Management Program may also require additional measures where construction activities will impact Guam’s coastal zone.

Projects must show compliance with 11 ESC standards
ESC Standards

1. Minimize unnecessary clearing and grading to preserve existing natural areas

2. Protect waterways (minimum 25-foot buffer) and stabilize drainage ways

3. Phase construction to limit soil exposure

4. Stabilize exposed soils immediately (~14 days)

5. Protect steep slopes and cuts from erosion

6. Install perimeter controls to keep sediment on site

7. Employ advanced sediment settling control devices

8. Train and certify contractors on ESC plan implementation

9. Conduct a pre-permit site meeting and adjust plan if necessary

10. Where feasible, schedule construction during dry season

11. Maintain ESC controls throughout the entire construction process
To meet ESC standards, the order of construction should follow these steps:

1. Hold Pre-permit Meeting
2. Clear for ESC Practices
3. Minimize Site Clearing
4. Perimeter Controls
5. Temporary Stabilization
6. Install Permanent BMPs
7. Permanent Stabilization
Proper Construction Sequencing

1. Hold pre-permit meeting

2. Mark limits of disturbance to protect waterway buffer, existing vegetation, and other resources

3. Clear/grub areas necessary to construct ESC practices

4. Stabilize construction entrance and install necessary perimeter controls and diversions

5. Install temporary sediment trapping devices and runoff conveyance systems

6. Complete clearing and rough grading where necessary (minimized and phased)

7. Provide temporary stabilization with vegetation or mulch for inactive, disturbed areas

8. Construct utilities, roads, and buildings

9. Convert/install permanent stormwater practices

10. Stabilize with permanent vegetation

11. Remove temporary ESC devices

(Adapted from: Center for Watershed Protection)

Roles and Responsibilities

Proper ESC is everyone’s responsibility. The role site supervisors, laborers, and equipment operators take in implementing the ESC plan is critical for success.

Contractors and Site Supervisors

☑ Make sure all permits are approved before starting work.

☑ Be trained in ESC standards, practice installation, and maintenance procedures.

☑ Educate operators and site workers on the function and proper installation of ESC practices.

☑ Install ESC practices according to the ESC plan and in accordance with the manufacturer of the ESC materials.

☑ Protect waterways, trees, and other natural areas from construction activities by keeping equipment within defined limits of disturbance.

☑ Follow appropriate construction sequencing.

☑ Establish a self-inspection schedule and designate a person responsible for conducting routine inspections of ESC. Make sure practices are maintained, repaired, and reinstalled when necessary.

☑ Communicate with engineer, owner, and/or inspector any concerns related to ESC.

☑ Properly remove practices at end of construction only after site is permanently stabilized.

Laborers and Heavy Equipment Operators

☑ Understand how individual ESC practices are supposed to work in order to properly install them.

☑ Follow grading plans and be proactive about stabilizing exposed soils and slopes through proper grading and surface roughening techniques.
Know where the limits of disturbance and clearing are to avoid damage to trees and streams.

Plan equipment routes to minimize excessive soil compaction between work areas and stockpile locations.

Do not track mud off site on equipment tires.

Be aware of areas on site where erosion is likely to occur and to notify site supervisors of issues and potential solutions.

Be sure to apply surface roughening techniques at the end of each day to stabilize slopes where you are working.

Don’t walk away from a site without ensuring that proper ESC measures are in place, in case it rains overnight.

Inspectors

Understand regulations affecting construction site activities and proper ESC practice application.

Be familiar with the approved ESC plan, construction sequencing, and specifications.

Communicate expectations for cooperative ESC implementation.

Inspect site weekly, within 24 hours of major rainfall event, and at critical points during the construction process.

Anticipate where ESC problems may occur.

Ensure ESC practices are properly installed, maintained, and performing adequately. Provide input for improvement or minor modifications in the field, as needed.

Maintain detailed records of inspections with reports, photos, and rainfall records.

Establish clear timeframe for corrective actions to be completed.

Follow up. Initiate any enforcement actions.
Before extensive clearing and grading occurs, barriers should be installed at vehicle entrances and at key perimeter locations to keep sediment from leaving the site.
Definition
The limit of disturbance, or limit of work, is the physical marker of the boundary between areas that will be disturbed during construction (e.g., cleared, graded) and areas that will remain in their existing condition. The limit of disturbance should be clearly denoted in the construction drawings and be marked in the field prior to site clearing. Typically, orange safety fencing, flagging, silt fencing, or other highly visible barrier is used to mark the limit of disturbance and alert workers. If appropriate, use signage in multiple languages.

Heavy equipment operators should not begin site clearing until the limit of disturbance has been installed.

Installation
Before clearing, mark areas to be preserved with plastic construction fencing, flagging, and/or signage. Install fencing along the limit of work as shown in the construction drawings, which may be along property boundary, preserved areas (e.g., buffers), archeological sites, etc.

Locate temporary roadways, material stockpiles, and staging areas to avoid vegetation and prevent unnecessary clearing. Prohibit heavy equipment, vehicle traffic, and storage of construction materials within protected areas. Most importantly, instruct all site personnel to honor protective devices.

Maintenance Required
During construction, the limits of disturbance should remain clearly marked at all times. Verify that protective measures remain in place and restore damaged protection measures immediately. Serious tree injuries should be attended to by a tree specialist, especially damage to large and/or important native trees.
Example of highly visible limit of disturbance fencing, in this case chain link with dust control fabric. Silt fence installed inside boundary.

Failure to adequately maintain/protect a 25-foot buffer zone between the stream and construction activities. Encroachment reduces buffer filtering capacity and can lead to in-stream sediment deposition.

= good use of practice  = poor use of practice

**Common Problems**

- **No limit of work was installed at all.** This could lead to clearing in designated protected areas.

- **The limit of disturbance is not installed in the correct location per design plans.** Verify placement prior to clearing.

- **Limits are not clearly marked.** Make sure to use highly visible signage and fencing and repair any damage immediately after it is noticed.

- **Sediment discharge observed in protected areas.** Remove deposited sediment and install additional practices to prevent sedimentation.
**Definition**
Existing trees located inside the limit of disturbance that are not to be removed need protection during construction. Tree protection generally involves the installation of temporary fencing or other high-visibility barrier that help prevent equipment operators from nicking trunks, damaging low lying branches, and stockpiling or grading close to roots.

**Design & Installation**
- Before clearing, mark areas to be preserved. Use temporary wood fencing, plastic construction fencing, flagging, and/or signage.
- Install fencing outside of the tree’s dripline, where possible, to protect roots.
- Instruct all workers to honor protective devices.
- Prohibit heavy equipment, vehicular traffic, or storage of construction materials within the protected area.
- Consider the impact of grade changes to vegetation and roots.
- Do not remove until site cleanup and final stabilization is complete.

**Maintenance Required**
During construction, tree protection should remain clearly marked at all times. Verify that protective measures remain in place. Restore damaged protection measures immediately. Serious tree injuries shall be attended to by a tree specialist.

**Common Problems**
- **Tree shields wrapped around trunk don’t protect roots or branches.** Install construction fencing at dripline or an adequate distance from trunk.
- **Trunk scraped by equipment.** Have arborist look at tree to determine if it will survive. Remove tree if it is not expected to survive. Replant one or more additional trees as needed to compensate for loss.
- **Large tree roots cut or exposed.** Extend fencing beyond dripline to protect roots. Remove the ends of damaged roots with a smooth cut. Cover exposed roots with soil.
- **Soil compacted over roots.** Aerate soil by punching holes 12 inches deep, 18 inches apart.
Good use of highly visible construction fencing to mark limit of disturbance. Additional bilingual signage installed to identify area as protected.

Example of how trees get inadvertently damaged from equipment operating too close.

Figure 2.1. (a) Do not trench or excavate within the root zone of trees, this may sever roots. Root severance can cause instability, creating a hazardous situation. (b) To prevent any vehicles or machinery from operating over the root zone, install tree protection fencing. Fencing must be strong and appropriate to the degree of construction activity taking place on the site, and must be located at or beyond the dripline (Source: Auckland, New Zealand, 2009).
Definition
Stabilized construction entrances are temporary crushed rock pads located at all points where vehicles enter or leave a construction site. The purpose of a stabilized entrance is to reduce the tracking of sediment/mud from the site onto paved roads and parking lots.

Design & Installation
▪ Locate entrance to provide for maximum use by all construction vehicles.

▪ Place woven or non-woven geotextile fabric over entire area to be covered with rock (see CNMI/Guam Stormwater Manual for fabric specifications for heavy duty vs. light duty roads).

▪ Spread minimum 6-inch thick layer of 1- to 4-inch rock, or reclaimed/recycled concrete equivalent on top of fabric.

▪ Minimum width of entrance should be 12 feet (24 feet if only access point), but not less than the full width of access point. Ends should be tapered to meet street.

▪ Minimum length of 50 feet (30 feet on single residential lots).

▪ Piping of surface water under entrance or a moundable berm shall be provided as required (Figure 2.2).

▪ When necessary, wheels shall be cleaned to remove sediment prior to leaving site. If a washing area is required, drainage should be directed to a sediment trap rather than storm drains, ditches, or watercourses.

Use available crushed rock or recycled concrete equivalent for temporary construction entrance.
**Maintenance Required**
The condition of crushed rock should be monitored periodically and maintained after heavy use or heavy rainfall to prevent tracking or flowing of sediment onto rights-of-way. This may require periodic top dressing with additional rock.

All sediment spilled, dropped, or washed onto public rights-of-way must be removed immediately and more rock added as needed.

**Common Problems**
- **Crushed rock compacted into ground.** Install layer of fabric underneath and reapply rock.
- **Crushed rock full of sediment.** Top-dress with additional rock or wash and drain to sediment trapping device.
- **Vehicles going around stabilized entrance.** Be sure to taper edges to street. Expand entrance width or install barriers to direct traffic to entrance.

Figure 2.2. Stabilized construction entrance with optional mountable berm.
Good example of a stabilized entrance pad. Fabric is installed beneath rock layer. Fencing used to keep traffic on pad and block sediment from surrounding area (Source: University of Illinois).

Washing tires of construction vehicles is a good way to prevent sediment from leaving the site. The dirty wash water should be directed to a sediment trapping device.

Sediment tracking and buildup shows that entrance has not been maintained. Add, wash, or replace aggregate as necessary.
SILT FENCING

Definition
A temporary barrier of geotextile fabric, silt fencing is installed across a slope, around stockpiles, or along a perimeter. The purpose of a silt fence is to intercept sediment-laden runoff from small drainage areas of disturbed soil, slow runoff velocity, and allow sediment to settle out.

Design & Installation
- Install before extensive land clearing activities begin.
- Place fencing close to disturbed area, but ~10 feet from toe of slope to allow for sediment build up and maintenance access. The area beyond the fence should be undisturbed or stabilized.
- Install perpendicular to flow direction. Turn ends uphill to prevent bypass of water around fence.
- On long shallow slopes, install multiple rows of fencing at separation distances based on slope steepness (Table 2.1 and Figure 2.4).
- Silt fence should receive only sheet flow, not concentrated flow.

<table>
<thead>
<tr>
<th>Slope Steepness</th>
<th>Maximum Length (ft)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2:1</td>
<td>25</td>
</tr>
<tr>
<td>3:1</td>
<td>50</td>
</tr>
<tr>
<td>4:1</td>
<td>75</td>
</tr>
<tr>
<td>5:1 or flatter</td>
<td>100</td>
</tr>
</tbody>
</table>

Silt fences often fail due to poor installation or lack of maintenance.

- Dig 4-inch wide by 6-inch deep trench. Install posts every 5-10 feet on downhill side of trench at least 16 inches deep. Use “T” or “U” type steel or sturdy wooden posts (3 square inch cross section).
- Place fabric along bottom of trench. Attach to posts with wire or plastic ties every ½ foot. Fold and tie posts together to overlap fabric at ends.
- Backfill trench with soil and compact.
- Reinforce fabric with heavy wire support fencing to prevent collapse where necessary (Figure 2.3).
Maintenance Required
Inspect daily. Repair if sagging, flapping, or bulging is noticeable, or if erosion or spillover is observed. Remove sediment and debris when build up reaches 1/3 height of fencing. If site is inactive, continue to inspect after every rain event.

Common Problems
- **Not maintained.** Should be inspected daily. Remove accumulated sediment when buildup is 1/3 height of fence, and replace torn fabric immediately.
- **Not trenched properly.** Reinstall to prevent flow from going underneath.
- **Stakes placed on uphill side of fence.** Reinstall stakes 5-10 feet apart on downhill side.
- **Installed across concentrated flow path** (i.e., swale or stream). Identify source of concentrated flow and re-evaluate placement of silt fence. Use different ESC practice if needed.
- **Flow overtops or bypasses fencing.** Add uphill row of fencing, add wire support, or turn ends uphill.
Figure 2.4. Reasons Silt Fences Fail (Adapted from: Center for Watershed Protection)

- Silt fence is **not aligned parallel** to slope contours.
- Fence receives **concentrated flow**.
- Fence **not properly trenched** into ground.
- **Spacing between posts** is too great.
Fence placed **uphill** of disturbed area.

**Slope and/or length of slope** too great for fence.

Ends do not **curve uphill** to prevent bypass.

**Sediment deposits** behind fence not removed in time to prevent failure.
Good use of fencing around stockpile. Area outside of fencing is stabilized with grass. Leave enough space behind fence for maintenance access.

Workers installing silt fence along the perimeter of construction area. Be sure to locate fencing based on ESC needs, not just placed around the property boundary.

The bottom of silt fencing should be securely trenched, not covered with a thin layer of dirt. Trench should be at least 6-8 inches deep, backfilled, and compacted.

Concentrated flow down this slope and improper use/installation of the silt fence have resulted in practice failure and sediment discharge beyond the site.
SILT FENCE ALTERNATIVES

Definition
Because of the high failure rate and extensive maintenance burden of silt fences, consider using some of these alternatives:

Berms: Linear barrier of compacted soil or sand/gravel bags used to block or divert runoff (see Chapter 3, Diversion Berms).

Compost socks: Mesh tubes (also called filter socks) filled by blower with organic or wood mulch. These flow through filters can be used on pavement, around site perimeters, as check dams, and as inlet protection (Figure 2.5).

Straw Wattles: Mesh or netting tube filled with straw. Light use only - as they do not hold up well to heavy flows.

Design, Installation, & Maintenance
Follow manufacturer’s installation and maintenance instructions.

Figure 2.5. Typical filter sock installation (Adapted from: Iowa Statewide Urban Design and Specifications Manual).
Compost socks can be used on paved surfaces to trap sediment.

Construction fencing is not an approved alternative to silt fence.

Socks can be used on slopes, but remember to properly maintain practice by removing excessive sediment that has built up behind it.

Straw wattles do not last very long, losing their shape and capacity to filter after one or two storms.
**Definition**
A turbidity curtain is a flexible, floating barrier used to contain suspended sediment along a shoreline or within a waterbody for a short period of time. This curtain has a flotation system at the top and is weighted or anchored at the bottom.

**Design & Installation**
- Various types are available, see manufacturer’s instructions for your application.
- Do not use across flowing waters. Use in calm water surfaces.
- Curtain height shall be 20% greater than current water depth to allow for changing water levels.
- Remove obstacles and debris from area prior to installation.
- Locate around perimeter of construction site and firmly anchor in place. Place shoreline anchors outside of areas to be disturbed by construction equipment (Figure 2.6).
- For shallow installations, curtain can be secured by staking rather than using flotation system.
- Anchor curtain toe as needed depending on wave action and boat traffic.

**Maintenance Required**
Inspect curtain weekly, and check anchors and attachments after heavy winds or wave action. All floating debris shall be removed to prevent damage to the curtain. Any problem or failure of the curtain must be repaired immediately.

When removal of sediment deposited behind curtain is necessary, remove by hand. Allow 24 hours for sediment to settle before removing the curtain. Remove curtain by carefully pulling it towards shoreline to minimize the release of remaining sediment. All removed sediment should be disposed of properly.

*The turbidity curtain is the last line of defense for land-based construction runoff, and must be used in conjunction with other ESC practices on site.*
Turbidity curtains should not be the only ESC measure keeping sediment on site. They are the last line of defence.

While this is installed correctly, erodible materials should not be stored in waterway regardless of ESC practice usage. Be sure to firmly anchor ends of curtain to shoreline.

Figure 2.6. Typical turbidity curtain with flotation and anchoring devices.
Stabilized conveyance systems can be used to divert runoff into trapping devices or around disturbed areas.

Ponding of runoff behind dams allows sediment to drop out before discharge.
Definition
Berms and swales, depending on their location, can be used to divert “clean” runoff around disturbed areas, or to move “dirty” runoff to sediment traps.

Berms or dikes are typically mounds of compacted soil or sand bags placed at the top or base of slopes, along the site perimeter, or across exposed areas (Figure 3.1).

Swales are temporary channels used to convey runoff to a sediment trapping device (Figure 3.2).

Design & Installation
▪ Do not construct diversion practices outside the site boundary.
▪ Do not install diversions to redirect existing streams around your site.
▪ All berms should be compacted by heavy equipment, except for the combined dike/swale (Figure 3.3) and sand bag berms.
▪ Berms and swales should be stabilized within 1 week of installation.
▪ All berms and swales must have a positive, uninterrupted grade to a stabilized outlet. Typically minimum of 0.5% to 20% maximum slope (8% max on combined berm/swales, or if not using ESC matting or riprap).
▪ Outlets must slow runoff velocity to prevent erosion. Convey “dirty” runoff to a sediment trap.
▪ The flow of any existing natural drainage shall not be impeded or changed without a written waiver from the Administrator.

Maintenance Required
Full length of berms and swales should be inspected weekly and after every rain event in case of damage.

Common Problems
1. Drainage area too large. Install additional practices to reduce contributing drainage area and prevent erosion and overtopping.
2. Berms not stabilized. Stabilize exposed soils with temporary seeding, mulch, matting, or rock.
3. Erosion at outlets. Relocate or redesign outlet to slow runoff velocity and dissipate flow.
4. Too steep. Install matting or riprap to reduce erosion.
Figure 3.1. Earth berm cross section for different sized drainage areas.

Figure 3.2. Diversion swale cross section with 2:1 side slopes.

Figure 3.3. Combined berm/swale cross section.
Good use of a diversion berm at the base of a slope and along the perimeter to protect adjacent natural areas from construction site runoff. The berm was stabilized with erosion control matting and grass seed.

This diversion swale directs flows to a sediment trap. Do not divert “dirty” runoff to streams.

Great use of an earth berm to collect and divert runoff from the site into a stabilized outlet at the top of a ponding basin (behind chain fence on right). The berm should be stabilized with erosion control blankets or vegetation.
CHECK DAMS

Definition
Small check dams constructed of rock, sand bags, compost socks, or other durable materials are placed across an open drainage channel to reduce erosive runoff flows and allow sediment to settle out.

Design & Installation
▪ Maximum 2 acres drainage to the dam.
▪ Anchor check dams in the channel by a cutoff trench 1 ½ feet wide by ½ foot deep and lined with filter fabric.
▪ Use a well-graded rock matrix 2 to 9 inches in size. For other materials, follow manufacturer’s specifications.
▪ Height of check dam less than 2 feet. Center shall be 9 inches lower than sides at natural ground elevation (Figure 3.4). Side slopes shall be 2:1 or flatter. Be sure to tie into banks.
▪ Space dams as directed in site plan. The top of the downstream dam should be at the same elevation as the toe of the upstream dam (Table 3.1).

Maintenance Required
The check dams should be inspected after each runoff event. Correct all damage immediately. Replace rocks as needed. Make sure culverts or other structures are not blocked by displaced check dam rocks.

Common Problems
▪ Erosion occurring between structures. Evaluate spacing. Install erosion control liner.
▪ Sediment accumulation behind dams. Remove sediment behind dam to allow channel to drain and prevent overtopping.
▪ Dams dislodged by heavy flow. Reduce drainage area or install additional check dams. Use larger size rock. Better anchoring.

Table 3.1. Standard spacing (MDE, 1994).

Do not use silt fence for check dams, which should extend fully across ditch to prevent erosive bypass and have a lower center to allow for controlled spillover.

Good example of rock check dams that are lower in the center and extend fully across the channel to avoid run around.

Figure 3.4. Proper spacing and cross section of rock check dam.
This channel needs some check dams to slow erosive velocities.

The center of this check dam is not lower than the sides, which can lead to run-around and bank erosion during high flows.

Silt fence with sandbags may be used in a pinch, but must extend up sides and have a notched center. Prepare for repair.

This check dam is a combination of stone and vetiver grass.
Definition
Vegetated or lined channels are used to safely convey flows from stabilized areas or outlets without damage from erosion. Waterways are typically stabilized with grass, erosion control matting, rock rip rap, gabions, or concrete depending on slope, soil, and runoff velocity.

Table 3.2 summarizes some key features of vegetated versus lined waterways.

Design & Installation
▪ Clear foundation of trees, stumps, roots, loose rock, or other objectionable material.

▪ Excavate and install as shown on the plans (Figure 3.5). Backfill over-excavated areas with moist soil compacted to the density of the surrounding material.

▪ Do not allow abrupt deviations from design grade or horizontal alignment.

▪ Stabilize channels according to specifications.

Table 3.2. Features of Various Waterways

<table>
<thead>
<tr>
<th>Vegetated Waterways</th>
<th>Lined Waterways</th>
</tr>
</thead>
<tbody>
<tr>
<td>▪ May require subsurface drainage or additional outlets to reduce wet spots.</td>
<td>▪ Used when vegetation will not prevent erosion (&gt;6% slopes).</td>
</tr>
<tr>
<td>▪ Seed with grass as soon as practical if low gradient (&lt;3% slope).</td>
<td>▪ Steepness of side slopes based on liner type (see 2006 CNMI/Guam Stormwater Manual).</td>
</tr>
<tr>
<td>▪ Use sod and erosion control matting, particularly along centerline at moderate gradient (3-6% slope).</td>
<td>▪ Minimum lining thickness of 4 inches for concrete lining, or 1½ times the maximum rock size for rip rap.</td>
</tr>
<tr>
<td>▪ Vegetation must be established before use.</td>
<td>▪ Weep holes and underdrains should be provided for concrete.</td>
</tr>
</tbody>
</table>
▪ Follow manufacturer’s instructions for installing erosion control matting in channels (Figure 3.6).

▪ Hard linings shall be installed as shown on the plans. Non-woven geotextiles and cutoff walls may be used to prevent undermining.

▪ Do not use until fully stabilized.

▪ Requires a stable outlet that does not cause erosion at discharge.

**Maintenance Required**

Pavement or lining should be maintained as built to prevent undermining and deterioration. Existing trees next to pavements should be removed, as roots can cause uplift damage. Vegetation next to pavement should be maintained in good condition to prevent scouring if overtopped.

**Common Problems**

▪ **Vegetation not establishing.**
  Use erosion control matting or sod. Install additional outlets or underdrain system.

▪ **Out-of-bank flows are problematic.** Reduce flows to channel, or redesign.

▪ **Gullies forming in vegetated channel.** Use liner in centerline of vegetated channel.

▪ **Erosion beneath rock channels.** Make sure filter fabric was installed.
Concrete-lined waterways are effective for steep slopes and can be used as permanent drainage features.

Love the practice, but will require proper installation at discharge pipe, proper layout and overlap along channel bottom, and proper trenching at top of slope to be effective.

Figure 3.6. Diagram of erosion control matting used to line channel. (Adapted from State of California DOT Construction Site BMPs Manual, 2003)
**Definition**
Large basins and small traps are temporary ponding structures used to collect runoff and allow sediment to settle out before runoff leaves the site. Basins and traps are formed by an embankment and/or excavation.

**Design & Installation**
- Construct before earth-moving activities begin. Clear embankment area of all vegetation and debris.
- Design and construction of embankments, basins, and traps must comply with all engineering specifications (Table 3.3).
- Locate traps (Figure 3.7) and basins (Figure 3.8) to obtain maximum storage, ease cleanout, and minimize interference with construction activities.
- Where outlets required, maximize distance between inlet and outlet.
- All pipe connections should be watertight.
- Install water-permeable covers on basins to prevent trash and debris from clogging pipe. Dewatering holes in base of riser should be covered by filter fabric or rock. No holes allowed in outflow pipe.

**Table 3.3. Differences Between Basins and Traps**

</tbody>
</table>
Perforated risers should be wrapped in wire and filter cloth. Do not cover top of riser. No perforation within 6 inches of outflow pipe allowed.

- Outlets should be constructed and maintained to prevent sediment from leaving the trap and erosion from occurring below dam.

- Stabilize all side slopes, inlets and basin outlets (including spillway/energy dissipater).

* If basin is permanent, temporary riser will need to be replaced with permanent water quality control outlet structure.

**Maintenance Required**

Repair any damage daily. Remove sediment to original design volume when reduced by half (e.g., mark height on riser or sediment marker). Dispose of sediment according to approved site plan. In no case should...

Figure 3.7. Examples of excavated traps with (a) pipe or (b) rock outlet (AS-EPA Guidance Manual for Runoff Control, 2001). Traps located in limestone may not need an outlet.
removed sediments be disposed of in streams or other natural areas.

Do not remove basin until site has been fully stabilized for at least 30 days. Remove water by pumping or cutting riser prior to removing dam. Do not allow sediment to flush into a stream or drainage way. Basin sediments must be removed, safely disposed of, and backfilled with a structural fill.

*If converting to permanent practice, basin should be cleaned of deposited sediment and re-graded to meet new design specifications.

**Common Problems**

- **Outlet pipe clogged with debris.** Clean pipe, install filter fabric or trash rack cover.

- **Basin slopes eroding.** Stabilize slopes with rock, vegetation, or matting. Pay close attention to inlets.

- **Excessive sediment buildup.** Remove sediment to retain holding capacity. Do not allow sediment to build up higher than 1 foot below spillway.

- **Upstream drainage too large.** Have engineer check drainage area calculations. Use other or additional practices.

Figure 3.8. Sediment basin spillway profile. Basins located in limestone may not need an outlet.
Good use of lined diversion swale to convey runoff to a series of sediment traps.

Large sediment basin to be converted to permanent stormwater practice once construction complete and accumulated sediment is removed. Good distance from inlet to outlet riser. Good stabilization of side slopes and spillway.
Two-celled sediment basin with upper sediment forebay. Use plywood baffles to increase residence time to allow sediment to settle out. Vegetation stabilizes side slopes.

Large sediment basin with inlet pipe, outlet riser, and emergency spillway.
**Definition**

Sometimes there is the need to pump “dirty” water out of excavations or from construction projects along shorelines and stream crossings. Dewatering devices should be used to remove sediment before that water is discharged. Typical devices include:

**Sump pits** are holes dug into an area that requires dewatering into which a perforated vertical standpipe wrapped in gravel is inserted. Water is pumped from the center of the pipe and filtered through gravel (Figure 3.9).

**Bag Filters** are square or rectangular bags made of non-woven geotextile fabric that trap sand, silt, and fines inside the bag as water flows through the fabric (Figure 3.10). Bags come in many sizes.

**Weir Tanks** are containers with a series of baffles that create compartments to trap sediment.

**Containment Areas** are excavated areas surrounded by gravel, silt fence and/or other sediment barriers used for secondary dewatering treatment (Figure 3.11).

**Design & Installation**

▪ Size devices and pumps based on expected volumes and flow rates. Table 3.4 has sizing guidance for containment areas. Storage for tanks ($\text{ft}^3$) is equal to the pump discharge (GPM) x 16, assuming 2 hrs of residence time.

▪ Discharge from pits, filters, and tanks should be directed to another dewatering device, sediment basin, or stabilized containment area.

▪ Follow manufacturer’s installation and maintenance instructions.

▪ Do not use in place of sediment traps or other ESC practices.

▪ Locate dewatering devices for ease of clean-out and to minimize the interference with construction and pedestrian activities.

*Sump pits are used to filter out coarse particles during dewatering.*

</table>

Figure 3.11. Example schematic showing a stone and block dewatering containment area (Horsley Witten Group).
Good use of containment area to surround dewatering bag and provide additional treatment. Note that this practice is in need of maintenance.

Common Problems
- **Discharge still turbid.** Use the appropriate pump size and device dimensions. Add another filtering practice. Remove accumulated sediment.

- **Sump pit not filtering.** Consider wrapping perforated pipe in filter fabric. Be careful, this could clog.

- **Bag explosion.** Too much sediment accumulation. Increase bag size and maintenance frequency.

Maintenance Required
Inspect and monitor dewatering practices on an hourly basis while pumps are running. Make sure that discharges are not causing additional erosion and sedimentation.

Follow manufacturer’s instructions for removing sediment in reusable bags, or for determining when bags need to be replaced. Have a plan for proper disposal procedures.
**Definition**
For culvert, bridge, or shoreline projects, isolating the construction area from surrounding waters may be necessary to create a dry work area and minimize contact of flowing water with exposed soils. Because these activities are in the water resource, proper permitting, design, and practice maintenance are critical.

*Cofferdams* or *impervious dikes* are used to isolate the work area from a surrounding waterbody. They can be made from welded metal sheet piling, inflatable bladders, sandbags, or other materials (Figure 3.12).

*Piped diversions* and *temporary channels* are used to convey streams around construction until the site has been stabilized. Channels should be stabilized with stone, liners, or erosion control blankets (Figure 3.13). Pumps or the natural current will move water through these diversions.

**Design & Installation**
- Specify the appropriately sized practice (and pumps, if needed) for length of site and anticipated flows.
- Size channels to convey at least the 2-yr storm with a maximum of 2:1 side slopes. Protect channel and top of bank from erosion (e.g., liners for channels; berms/silt fence for top of bank). Do not install in fill material.
- Use geotextile and/or stone below pipes.
- Be sure to anchor all pumps and pipes securely.
- Ensure a good seal for cofferdams by properly preparing the sub-grade.
- Minimize amount of disturbance at diversion points.
- Specify dewatering procedures.
- Try to work during the dry season.
- Do not use earthen dams.

**Maintenance Required**
Inspect and monitor daily to make sure dams are functioning properly. Where pumps are being used, inspect on an hourly basis. Make sure erosion is not occurring upstream or downstream of the diversions and that channel side-slopes are stable.
Figure 3.12. Examples of various materials used as cofferdams (Sources: NCDOT and Horsley Witten Group), and plan view schematic showing dewatering device (Horsley Witten Group).
Common Problems

▪ **Not sized appropriately.** Check your math and revise as necessary.

▪ **Erosion of channel and diversion points.** Stabilize area with appropriate erosion control practices.

▪ **Leaky cofferdam.** Depending on type of dam, reset structure, remove debris, or add an impermeable liner to re-create a proper seal.
**Piped diversion of stream using a bladder bag impervious barrier.**

**Working in the stream channel with no separation from stream flow.**

**Earthen berm and silt fence do not provide adequate isolation of work area.**

**Diversion of stream into a temporary rock channel while stabilizing existing channel during bridge reconstruction. Note use of silt fence at top of channel.**
Aggressive protection of slopes is critical since erosion can occur rapidly and contribute to extensive sediment transport and slope instability.
STABILIZATION WITH VEGETATION, MULCH, OR TOPSOIL

Definition
Covering an area of bare ground with vegetation, topsoil, mulch, or erosion control blankets for temporary or permanent erosion prevention is critical. Temporary stabilization is often needed because grading operations can last several months and extend into or through the rainy season. Final stabilization will be required for project close out.

Vegetative cover can be established through a combination of seeding techniques, topsoil amendments, and mulching to conserve moisture and control weeds.

Design & Installation
- Stabilize bare areas that will be untouched for more than 14 days, after final grading, at completion of construction, or when waiting for optimal planting time.
- Preserve existing topsoil in place where possible. Stockpile topsoil from excavated areas for later use.
- Complete rough and final grading. Remove large woody debris and other litter.
- Compact all fill material and roughen surface at least 12 inches deep in the area to be seeded.
- Amend soil and add fertilizer where necessary.
- Evenly apply seed mix per site plan specifications. Suitable plants include fast-growing and hardy species, such as grasses and legumes (Table 4.1).
- Apply mulch or chemical stabilizers at specified application rates after or in combination with seeding (hydroseeding). Tackifiers are useful on slopes to help anchor soils and seed mixes.
- As needed, install erosion control blankets to protect areas being stabilized.

Maintenance Required
Irrigate as necessary to establish plants. Reapply seed, mulch, or topsoil as needed to provide uniform stabilization. Maintain associated ESC practices to protect stabilization area until plants are fully established.

</table>

¹ List is not all-inclusive. Ideal species for seeding and stabilizing disturbed areas should be fast growing, non-invasive, tolerant of low fertility soils, and readily available.
² Tolerant of soil salinity and wind-bourne salt.
³ Tolerant of acidic, low fertility soil.
⁴ May have potential to become invasive.
⁵ Pure Live Seed (PLS). One bushel (bu) equals 1.25 cu. ft. **May need to double these seeding rates when hydroseeding.**
Formation of gullies and rills due to lack of stabilization. Presence of weeds indicates that soil has been exposed for a long period of time.

Good use of hydroseed and coir fiber logs on an exposed slope to help quickly establish vegetative cover. Any areas of bare soil that will not be touched for more than 14 days should be temporarily stabilized. Permanent stabilization is required at the end of the construction period.

Topsoil may be required in poor soil conditions. Here topsoil was spread evenly across surface to be seeded. Grass has started to grow.

Even clearing of flat areas requires stabilization as demonstrated here with wood chips.
Hydroseeding truck includes a mixing tank and dispersal cannon and hose.

The hydroseed mix is a combination of seed, paper or wood fiber mulch, binder (tackifier) product, and sometimes fertilizer.
Smooth area and remove soil clumps prior to application. Complete coverage means no bare spots.

50 lb. bags of wood fiber hydro mulch is added with seed and tackifier to make hydroseed slurry.

Figure 4.0. Successful stabilization is when an area of bare soil surface is at least 70% covered with established plants.
**Definition**

Surface roughening is a simple method to slow and minimize runoff by creating horizontal grooves, depressions, or steps that run parallel to the contour of the land. Surface roughening should be done in conjunction with other stabilization activities. Roughening measures include:

**Tracking:** Driving a crawler tractor up and down a slope, leaving the cleat tracks parallel to the slope contour (Figure 4.1). This is the easiest, but least effective of the roughening measures.

**Stair-step grading:** Benching or cutting stair-steps into slopes. Each step slopes towards the vertical wall (Figure 4.2). This works well with soils containing many small rocks.

**Grooving:** Use discs, spring harrows, or teeth on the bucket of a front-end loader to create series of small ridges and depressions.

---

Figure 4.1. Tracking with bulldozer (Source: US Army Corps of Engineers, 1997).
Surface terracing helps prevent erosion of slope surface. Should be combined with other stabilization techniques.

**Design & Installation**
- Perform surface roughening as soon as possible after the vegetation has been removed from the slope.
- Use with temporary seeding and temporary mulching to stabilize an area.
- Avoid excessive soil compaction when tracking, since this inhibits vegetation growth and causes higher runoff rates.
- When step-grading, ratio of vertical cut to horizontal distance should not be steeper than 2:1. Maximum step width/height is 4 feet.

  - For slopes steeper than 3:1 but less than 2:1, grooving should be used. Install grooves a minimum of 3 inches deep and maximum 15 inches apart.

**Maintenance Required**
May need to reapply at the end of each day until other stabilization practices are installed. Inspect every 7 calendar days and within 24 hours after major rainfall event. If rills appear, re-grade and re-seed immediately.

![Figure 4.2. Stair-step grading to protect slopes.](image)

Compacting the slope with bucket may create pathways for water to erode slope.
Definition
A pipe slope drain is a temporary pipe or flexible tubing with a stabilized entrance section, used where a concentrated flow of surface runoff must be conveyed down a slope without causing erosion.

Design & Installation
- The maximum allowable drainage area is 5 acres.
- Direct flows along top of slope to inlet using earth berms or other diversion practice (Figure 4.3).
- The inlet pipe leading to steep slope shall have a slope of 3% or steeper to prevent water pooling at top of slope.
- Cover inlet pipe at least a foot with hand-compacted earth berm.
- Use corrugated metal pipe with watertight connecting bands or durable, flexible tubing of the same diameter as inlet pipe (Table 4.2).
- Securely anchor flexible tubing to the slope with stakes as needed.
- Discharge pipe slope drain to riprap apron and then into a stabilized area, watercourse, or sediment trap.

Maintenance Required
Follow-up inspection and any needed maintenance should be performed after each storm.

Common Problems
- Erosion at discharge. Only discharge to stabilized area.
- Pipe rolls or separates. Stake in place. Replace connection bands.

Pipe slope drains are used to convey concentrated flow down a slope.

<table>

Flexible pipe slope drain used to convey concentrated flow down slope. Note placement of large rocks to slow velocity at discharge point. Drain may need to be anchored with stakes to prevent movement.

Use of pipe drain on this slope combined with other stabilization practices would prevent erosion.

Figure 4.3. Pipe slope drain discharging to sediment trapping device.
Definition
Temporary erosion control blankets (also called matting) are used to hold seed and soil in place, particularly on steep slopes. There are many types of products available made of biodegradable or synthetic materials.

Design & Installation
▪ Grade and compact area prior to installation.
▪ Remove large rocks, soil clods, vegetation, and other sharp objects.
▪ Amend soil, add fertilizer, and seed prior to installation.
▪ Always install according to manufacturer’s specifications.
▪ For slope installations:
  1. Dig anchor trench at top of slope (Figure 4.5).

3. Unroll matting down slope, ensuring direct contact with ground. Overlap edges a minimum of 3-6 inches.
4. Fasten with stakes/staples per manufacturer’s specification. Do not stretch.

Maintenance Required
Regular inspections should be made to identify cracks or tears in fabric, which should be repaired or replaced immediately. Synthetics may degrade in sunlight.

Common Problems
▪ Blanket slipping down slope. Re-anchor at top of slope. Use manufacturer’s staples/stakes and stapling pattern. Be sure roll is properly trenched at the top.

▪ Erosion occurs underneath the material. Make sure material is in contact with the ground. If not, remove blanket. Ensure smooth soil surface by raking out large clumps and stones.
Always install erosion control matting according to manufacturer’s specifications.

Figure 4.5. Erosion control blanket (Adapted from: State of California DOT Construction Site BMPs Manual, 2003).
Good coverage of slope with erosion control netting. Inspect routinely to make sure material is not torn, particularly if woody vegetation starts to grow up through material. Consider benefits of biodegradable vs synthetic materials.

Incorrect installation of coir blankets. No trenching and staking at top of slope, and matting not in close contact with soil surface.

Proper six inch deep anchor trench at top of slope holds coir matting in place. Backfill and stake fabric in trench.
Inlet protection practices prevent sediment from entering the drainage network until the site is stabilized and temporary ESC practices removed.
**Definition**
Various inlet protection devices can be used as temporary structures to keep silt, sediment, and construction debris from entering storm drains through open inlets. Practices should trap sediment while allowing water to slowly flow over or through materials.

**Design & Installation**
- Install protection device per specifications on site plan.
- Do not use in place of sediment traps, diversions, or other ESC practices.
- Limit drainage area to 1 acre or less per inlet device.
- The top elevations of these practices should provide storage and minimize bypass flow.
- Do not remove until drainage area is permanently stabilized.

**Excavated Drop Inlet Protection**
- Excavate side slopes less than 2:1.
- Depth should be between 1 to 2 feet as measured from top of inlet.
- Provide weep holes, protected by fabric and/or rock, to drain temporary pool (Figure 5.1).

**Fabric Drop Inlet Protection**
- Use approved filter fabric cut from continuous roll to avoid joints.
- The maximum height of the fabric above the inlet crest shall not exceed 1 ½ feet unless reinforced. Stake material using 2x4 inch wood or equivalent metal.
- Support stakes for fabric should be 3 feet long, spaced a maximum 3 feet apart.
- Drive stakes into ground a minimum of 18 inches as close to the inlet as possible.
- Trench fabric 1 foot and back fill. Fasten to stakes.

*Rock protection on outside of fabric can be added if available.*
Block and Rock Drop
Inlet Protection
- Double stack rows (1-2 feet above top of inlet) of concrete blocks around drop inlet. Do not use mortar. Recess the first row of blocks 2 inches below the top of inlet (Figure 5.2).
- Orient a few blocks on bottom row for dewatering. Cover openings with cloth or wire mesh to support rock.
- Use clean rock ½-¾ inch diameter placed 2 inches below top of block on 2:1 slope or flatter.

Curb Inlet Protection
- Install pre-fabricated products in front of curb inlet opening, extending 2 feet on either side. Allow for overflows at top into catch basin. Follow manufacturer’s specifications.
- For block and rock curb inlet protection, place single row of concrete blocks across inlet opening with open ends facing outward. Place wire mesh over open ends of blocks to support rocks. Pile washed rock (≤3 inch diameter) against mesh to top of blocks.
- For fabric and rock protection, install wooden frame with spacers

Figure 5.1. Excavated drop inlet protection with weep holes.
and overflow weir. Attach wire mesh and approved fabric to frame across inlet opening. Pile clean rock against mesh (2 inches minimum diameter). Structure should extend 2 feet on either side of inlet (Figure 5.3).

**Maintenance Required**

Inspect after each rain event and make repairs as needed. Check materials for proper anchorage and secure as necessary. Remove sediment when storage area is ½ full. Upon stabilization of the drainage area, remove all materials and sediment and dispose of properly. Seal weep holes.

Bring adjacent areas to grade, smooth, compact, and stabilize.

**Common Problems**

- **Excessive sediment entering inlet.** Ensure protection devices installed properly. Ensure soil is stabilized and upstream practices are installed.
- **Rock filter material clogged.** Pull rocks away from inlet, clean, or replace with new/washed rock.
- **Sediment accumulating outside of practice.** Remove when ½ full.
This prefabricated product is not suited for this type of inlet structure, since “dirty” flows enter drain directly through grated opening.

Sediment and trash at this outlet is an indicator that inlet protection has either failed or was not provided at all at this construction site.

Impermeable sand bags can cause flooding when used around inlets, and filter fabric can clog and tear. At this site, sand bags and fabric were partially removed to alleviate flooding, allowing dirty water into the inlet.

Good example of a compost sock inlet protection. When it rains, runoff filters through the compost, removing sediment and preventing flooding.
Definition
Rock should be placed around and below an outlet to stabilize the outlet, reduce the depth and velocity of discharge waters, and prevent downstream erosion. Outlet protection applies to culverts, outfalls from basins, and other conduits.

Design & Installation
- Design depends on the location (not at top of cuts or on slopes >10%) and tailwater depth. Follow specifications from approved drawings.
- Prepare subgrade as specified. Compact fill to density similar to surrounding material.
- Outlet aprons should be straight and flat. The end of the apron should be at same elevation as receiving channel or ground (Figure 5.4).
- Use rock riprap composed of a well-graded mixture of rock size specified in ESC plan.
- Apply layer of approved filter material between riprap and underlying soil surface. Overlaps should be >1 foot.
- Place rock with equipment in one operation. Avoid displacement of, or damage to, underlying material. Follow with hand placement when necessary.
- Place rock around and above outlets with no headwalls (Figure 5.5).

Maintenance Required
Once a riprap outlet has been installed, the maintenance needs are very low. It should be inspected after high flows for evidence of scour beneath the riprap or for dislodged rocks. Repairs should be made immediately.

Common Problems
- **High flows cause scour.** Replace filter fabric and rearrange rock appropriately.
- **Riprap dislodged.** Replace by hand.
- **Ripped filter cloth.** Cover with another piece of cloth or replace.
- **Riprap filled with sediment.** Evaluate upstream ESC practices. Remove sediment by hand.
Figure 5.4. Riprap outlet protection for discharge to unconfined section.

Figure 5.5. Protect outfalls without headwalls (Source: British Columbia, 2001).
To help stabilize rock apron and reduce undermining, filter fabric should be placed below the layer of riprap, not on top as shown here.

Good protection for outfall without a headwall. Discharge is dissipated in rock-lined pool which will then discharge as sheet flow to adjacent wetland. Berm behind outlet pipe is well stabilized with vegetation.

This outlet is discharging to a non-stable area on a slope, which will result in erosion and undermining of pipe structure. This muddy discharge also indicates a general lack of compliance with ESC principles.

This outlet and surrounding area is well stabilized with rock and grass. A little sediment is depositing in the apron.
Definition
Level spreaders are temporary (or permanent) devices that take concentrated flow from a pipe, berm, or swale and release it evenly over a wider area to prevent erosion and promote infiltration. Particularly useful where sheet flow discharges through vegetated buffers are possible.

Design & Installation
- Install in an undisturbed or finished area. Do not install on fill, or above a slope steeper than 10%.
- Maximum drainage area to spreader is 2.5 acres.
- Minimum depression depth of 6 inches behind lip.
- Spreader lip must be level (uniform height and zero grade) and reinforced with erosion control matting, concrete, or gravel.
- Runoff entering spreader must not contain significant sediment. An upstream sediment removal practice, forebay, and/or energy dissipater at inlet may be required.
- A level spreader should disperse onto a vegetated slope of less than 10:1.
- The lip can be constructed of grass for low flows or timber/concrete for higher flows.
- The length of the level spreader lip is dependent on the volume of water that must be discharged, but the minimum length for the level spreader lip is 6 feet.
- Make sure area below level spreader is stabilized and uniform.

Maintenance Required
Relatively low maintenance if installed correctly. Inspect regularly for sediment removal in sump and erosion at inlet/outlet. Repair as needed.

Level spreaders convert concentrated flow into non-erosive sheet flow.
Figure 5.6. Concrete and earth lipped level spreaders (Adapted from: RI Stormwater Manual and NC State University).
Concentrated flows are collected in small forebay and discharged into 6 inch deep “swale” before overflowing concrete lip as sheet flow (Source: NC State University).

Good application of level spreader at outfall from large ponding basin. Flows plunge into small pool, spread out evenly across level concrete lip, then sheet flow from lip across gravel into grass (Source: NC State University).
Road runoff, especially from unpaved roads, represents one of the largest sources of chronic sediment loading to coral reefs.
ESC During Road Construction

Temporary exposure of erodible soils during road construction and maintenance activities can impact water quality, road stability, and public safety.

Good road design and construction can minimize soil erosion and reduce drainage problems.

The challenge of road projects is that they are linear, space is limited, and there can be an added element of traffic management. Road projects are highly visible, so problems with ESC are noticeable to the public. Preventing erosion and controlling sediment requires use of ESC practices illustrated in Figure 6.1, including:

- Sediment barriers along perimeter
- Check dams in roadside ditches
- Slope stabilization
- Inlet protection
- Outlet protection
- Stockpile management
- Traffic safety

Unpaved Roads

Permanently unpaved roads can be chronic sources of sediment. To reduce sediment loads coming off unpaved roads:

- Design roads for minimal disruption of drainage patterns.
- Use outsloped roads with drain dips when fill slopes are stable.
- Use insloped roads with ditches, water bars, and cross drains if steep enough (2-8%) to prevent sediment deposition and ditch erosion.
- Vary road grades to reduce concentrated flows. Space drainage structures based on grade (Table 6.1).
- Prevent sediment transport by using changes in road grade or recessed cut slopes.
- Do not discharge drainage structures onto erodible soils or fill slopes without outfall protection (rock piles, logs, etc.). Direct road drainage through vegetation or other sediment trapping devices.
- Surface with crushed rock, concrete, or pavement if road is highly erodible or heavily used.
Exposed soils were hydroseeded and temporary inlet protection applied on road construction project. Active roadway is clean of sediment.

No erosion control provided and sediment is directly entering stream through culvert. Sediment tracked onto active roadway. No protective barrier blocking sediment from adjacent natural areas.

Figure 6.1. Illustration of ESC practices used during road construction.

1. Drop inlet protection
2. Silt fence along perimeter with j-hooks
3. Rock outlet protection
4. Traffic safety
Avoid situations where runoff from unpaved roads drains directly to drop inlets. This inlet will discharge sediment to waterways, and will quickly become clogged with debris and sediment causing road flooding.

Pave roads as soon as feasible. Good example of using wood check dams and rock fill to protect edge of pavement and slow down drainage.
Broad-based dips are wide (~20 feet) depressions used to convey ditch drainage across the road surface as sheet flow (Figure 6.2). Dips only work on roads with slopes <12%.

Water bars are narrow, earthen berms built across roads to divert road surface runoff into vegetated areas (Figure 6.3). To install:

1. Excavate a trench at a 30- to 45-degree angle across the road. Trench outlet should be at least 3 inches lower than the upper end.
2. Build a berm on the downhill side of the trench (12-inch distance between berm top and trench bottom).
3. Extend water bars slightly beyond both ends of the road. Direct diverted water into a stable, vegetated area, not into open water.

Cross drain and open-top culverts intercept ditch or road surface runoff and divert flows across the road in underground pipes or grated trenches. Piped culverts should be no less than 12 inches in diameter, angled at 30-45 degrees, have 2% slope, and covered with fill at a depth of ½ pipe diameter (Figure 6.4). The entry and outlet of pipe should be armored with rock or concrete.

Open-top culverts should be covered with a grate material that can handle vehicle loads.

Open-top culverts should be at least the width of a shovel for easy maintenance.

Figure 6.2. Wide dips allow ditch runoff to be directed by berms to flow across road to stable outlet. Not for use on grades greater than 12% (Adapted from: Wisconsin Department of Natural Resources).
Figure 6.3. Water bars divert surface flows and are not intended to intercept roadside ditches (Source: British Columbia, 2001).

Figure 6.4. Cross drain and open-top culverts carry water under road surface to stable discharge points (Adapted from: University of MN Extension Service).
Road Maintenance
Timely maintenance can prevent road-related sediment from entering streams and waterbodies.

- Inspect the road system at regular intervals, especially after heavy rainfall, to detect problems and to schedule repairs.

- Road surface erosion from ditch overflow indicates a need for unplugging culverts, cleaning ditches, additional cross drains or dips, or other ditch stabilization.

- Remove debris from culverts, outlets, and catch basins particularly before rainy season.

- Place the debris where it cannot be washed back into these structures or into open water.

- Stabilize fill slopes and maintain roadside vegetation.

- Keep traffic to a minimum during wet periods to reduce maintenance needs.

- Grading (shaping) as necessary to maintain proper surface drainage, remove potholes or ruts, or mix surface rock and fines.

- Grading should always push debris towards center of road for compacting or removal.

- Debris should never be pushed to side where it will form a berm and cause more erosion/maintenance problems.

- Avoid cutting the toe of cut slopes when grading roads or pulling ditches.

- If dust control agents are used, keep compounds from entering waterways.
Routine maintenance during construction and proper removal of temporary practices prior to final site stabilization will help ensure ESC compliance.
Inspections and Maintenance

Erosion and sediment control practices need to be inspected and maintained during all stages of the construction process to ensure proper function.

Routine maintenance by workers on site may include:

▪ Removing sediment tracked on to roads.
▪ Visual inspection and repair of silt fences and inlet protection devices.
▪ Replacing fencing and signage protecting trees and natural areas.
▪ Removal of accumulated sediment in traps, behind check dams, and on rock outlet aprons.
▪ Replacement of rock protection or filter fabric at outlets.
▪ Filling of rills and gullies.
▪ Irrigation for vegetative establishment.

Inspectors should:

▪ Conduct inspections at required frequency (every 14 days), after storm events, and during key times during construction (installation and closeout).
▪ Evaluate practice effectiveness.
▪ Evaluate locations where drainage leaves site, particularly along waterways, natural areas, and public roads.
▪ Use approved inspection forms and checklists if available (Table 7.1).

See maintenance requirements for individual ESC practices as described in Chapters 2–5.

</table>

**A. ESC Plan Review**

- Practices shown on ESC plan
- Practices installed as shown on ESC plan
- Sequence of construction followed
- Cut and fill conducted as described in ESC plan

**B. Sediment Barriers**

- Silt fence, turbidity curtain, or other barrier
- Installed/maintained correctly
- Construction entrance functions properly
- Amount of sediment tracked onto roads or deposited outside of barriers acceptable
- Are natural resource areas (i.e. streams or wetlands, sinkholes, seashore, trees) protected with barriers

**C. Diversions**

- Berms stabilized and performing adequately
- Swales/waterways constructed and functioning
- Extent of erosion at outlets meets standards

**D. Traps and Basins**

- Dams/overflows/risers constructed & functioning
- Slopes stabilized, particularly at inlets
- Good level of sediment accumulation

**E. Stabilization**

- Exposed soils and slopes protected from erosion
- Good vegetative establishment
- Erosion control matting/Pipe slope drains, mulch, or other practices installed/functions properly

**F. Inlet and Outlet Protection**

- Practices installed correctly around drop, yard, and curb inlets
- Rock outlet protections installed and maintained
- Sediment removal, erosion repairs, and other maintenance performed

**G. Other**

- Good offsite conditions at key discharge locations
- Previously required repairs have been made
- Discharge outlets and receiving water free of any sediment deposit
- Nonstructural BMPs being practiced

2012 ESC FIELD GUIDE FORM
Managing Trash, Supplies, and Materials
To keep debris and contaminants out of runoff during construction:

▪ Keep waste materials, stockpiles, and building supplies tied down or covered to protect from wind or stormwater.

▪ Manage designated areas for equipment washing, fueling, or servicing to prevent runoff.

▪ Store hazardous materials in a covered area to prevent contact with rain water. Concrete slabs and secondary containment berms are necessary to prevent spills from discharging into the environment.

▪ Recycle or reuse construction materials where possible to reduce waste going to landfill.

▪ Keep your site clean.

▪ Provide for proper sewage disposal.

Removing Temporary Practices
When construction is completed, all temporary ESC practices will need to be removed or converted to permanent structures. All construction waste will need to be disposed of properly and the site cleaned.

No site can be closed out or practices removed until vegetation is established on all bare soil areas and all ditches and slopes are stable.
When removing practices, be sure to:

▪ Remove accumulated sediment, regrade to new specifications, and replace/install water quality risers when converting temporary basins to permanent stormwater practices.

▪ Do not remove protection devices from inlets leading to basins until the basin has been stabilized.

▪ Fill in, grade, and seed traps/basins that have been removed. Double seeding rate where higher flows are expected.

▪ Remove all silt fencing. Disperse accumulated sediment on-site or dispose of properly.

▪ Replace dislodged rocks or soils at culverts and outlets. Stabilize with vegetation, and remove debris that could block outlets or clog inlets. Fill, grade, and stabilize eroded areas.

▪ Remove inlet protection devices once drainage area has been stabilized.

▪ Check ditches and channels to make sure banks and bottoms are stabilized. Bare areas should be re-seeded and/or repaired.

▪ Check areas where erosion control blankets were installed. Remove loose or excess materials. Re-seed bare areas.

**Permanent Stormwater Management**

To ensure proper drainage after construction, installation of permanent stormwater practices, drainage connections, and final site grading should be performed according to the stormwater plan. Special care should be given to make sure:

▪ All permanent stormwater facilities and drainage structures are installed as designed. If required, final “as-builts” should be submitted to the approval authority to ensure facilities were built according to approved plan.

▪ Final site grading directs stormwater to appropriate drainage structures.

▪ Paving of parking lots, roads, and other impervious areas maintains proper drainage patterns.

▪ Rooftop runoff drains to stabilized vegetated area or approved drainage structure.

▪ Permanent stormwater facilities and drainage structures are inspected before temporary practices are removed.

▪ Sediment or debris accumulated in stormwater practices is removed and disposed of properly.
Paving of parking area and use of trench drain (orange grating) occurred prior to installation of permanent stormwater controls downstream and final site stabilization. Drainage from parking lot discharges to exposed sediment rather than approved stormwater practice or drain pipe.

Final grading and paving at this site left inlet at a high point, causing surface runoff to bypass the stormdrain inlet.
Before this temporary sediment basin can be converted to a permanent stormwater practice, accumulated sediment will be removed, the basin regraded, and vegetation established.

Occupancy should not occur until vegetation has been permanently established.

Good example of designating an area for equipment washing. Before project closeout, these areas will need to be removed and trash, waste materials, and supplies cleaned up (Source: SoCal Sandbags).
